Director of Communications

Flease Feture To Engineering Staff

Initiation of Task Order E - Contract 616

1. The Office of Communications has a requirement for an Accessory Unit, AU-3 to enhance agent communication radio , Philadelphia, 25X1 Pennsylvania, has submitted a cost estimate and technical proposal for the development of such a device. 25X1 proposal, a copy of which is attached, has been carefully examined by this Office and is considered technically acceptable. 3. It is requested therefore that Task Order 2 under Contract 616 be initiated with 25X1 , according to the contractor's proposal. At-25X1 tached for this purpose is Requisition No. MEB 61-343 indicating that the allotment to be charged is 1179-0010-1000. Funds in the amount of \$4,318.72 have been encumbered for this purpose. The association of this equipment and the contract with the Agency is classified SECRET, although the equipment itself is unclassified. The cognizant project engineer for this program 25X1 11

•	Technical Proposal 61-54
	AUTOMATIC GAIN REGULATION SYSTEM FOR AUDIO AMPLIFIERS
	I. INTRODUCTION
·	This proposal describes a program for the development and design of a
	new and unique system for the automatic regulation of audio output to main-
	tain a level for intelligible reception in the presence of widely varying
	ambient noise conditions, while at the same time not allowing excessive volume under quiet conditions.
	The Automatic Gain Regulation System for Audio Amplifiers, subsequently
	referred to as the AGR System, is intended for use with radio receivers or
	other devices having an audio output up to approximately 1 mw. is currently doing work on a similar problem of automatic gain regulation at
	higher power levels with different requirements under Contract No. 616
	Task Order No. 3.
, !	II. APPROACH
	A. Objective
	This program will have as its objective the development and design
	of a miniature device which will regulate the output from a radio receiver
	or other equipment whose output may be up to 1 mw, providing automatic
	gain regulation based on ambient noise in such a way that the available
,	audio output will be adequate under high noise conditions and will not be
,	excessive when the ambient noise is at a low level. Inlouded in the ob-
	jective are the following specifications:
•	1. Power Input, up to 1 mw.
	2. Maximum Power Output, 100 microwatts into a 2.000 ohm load.
1	2. Maximum Power Output, 100 microwatts into a 2,000 ohm load.
	3. Output in the absence of Noise, 1 to 2 microwatts, with a maximum
•	automatic gain regulation of 17 to 20 db, providing an automatic control of
**	at least 2 to 100 microwatts under noise conditions varying from 0 to maximum
	4. Intelligibility. The Automatic Gain Regulation System will not
	appreciably alter Intelligibility for signal levels which would normally be
	understandable.

- 5. Size. The unit will have a volume of approximately one-half to one cubic inches and will have a flat form factor.
- 6. Power Source. Operating power of the Automatic Gain Regulation Device shall be derived from a small nickel cadmium storage cell which shall receive charging energy by rectification of the audio input to this device.

B. Present State Of The Art

Volume Compressors and Limiters have been developed using vacuum tubes and transistors, but operate at higher power levels and require more power supply energy than would be suitable for the proposed application.

C. Design Considerations

1. System

The system for the Automatic Gain Regulation Device is depicted in Figure 1 in the form of a block diagram. The Audio Source 1, delivering 1 mw maximum power from a 2,000 ohm impedance, drives a pre-attenuator 3. The output of this attenuator is fed to a voltage controlled attenuator 7 and in turn drives the output 8 which feeds a 2,000 ohm load and supplies up to 100 microwatts of power. The input audio signal is also fed to a solid state rectifier and supply 2. It is anticipated that this supply will be used to maintain the charge on a nickel cadmium storage cell. A noise sensing microphone 4, feeds a high gain noise amplifier 5 whose output is rectified by a noise rectifier 6 and filtered to provide the AGR voltage which is applied to the voltage controlled attenuator 7.

Miniature transistors, diodes and miniature components will be used to achieve the size and power efficiency requirements in this device.

2. Theoretical Considerations

a. Signal Level Requirements

Tests have been conducted which established that audio power levels above 50 microwatts may be heard by an individual who is not using the equipment under low ambient noise conditions. Tests also show that an efficient headphone may require as low as 1 to 5 microwatts for audibility under low ambient noise conditions. Conversely, high noise conditions may require as much as 50 or more microwatts to allow intelligible reception. Therefore, the proposed automatic gain regulation will provide approximately 17 to 20 db of audio output control.

b. Methods of Gain Regulation

The voltage controlled attenuator, Item 7 of Figure 1, may be in the form of a variable series or shunt impedance. Methods of varying this impedance include the use of transistors and diodes. In the case of the diode, these may be applied in the form of "L" or "TEE" Attenuators. One of the problems associated with this type of device are the nonlinear characteristics for varying signal levels. In the case of the diode attenuator arrangement, use of a low level audio signal and operation on a lower part of the curve can produce linear operation with minimum distortion. The pre-attenuator 3, will be used to establish the proper input level to the voltage controlled attenuator.

c. Noise and AGR Circuit

A miniature noise sensing microphone 4, will be used to sense the ambient noise level. This microphone will be a flat miniature type and may be mounted on the front of the Automatic Gain Regulation Unit, thus forming a part of the housing. The high gain noise amplifier 5, may use as many as three (3) miniature transistors with an overall gain of approximately 70 db. The output of the noise amplifier will be rectified and filtered with the proper time constants to produce the DC voltage which will be applied to the voltage controlled attenuator 7. The output filter of the noise rectifier will have a short charging time constant so that it will respond quickly to an increased noise level to avoid missing the first part of a word. The proper discharge time constant will be determined by experiment, but is expected to be between 2/10 and 1/2 second.

3. Power Supply

The power supply which is proposed, will be a small nickel-cadmium storage cell having a potential of approximately 1.3 volts. A rectifier 2, shown in Figure 1 will derive power from the 1 mw audio source and this will be used to charge on the storage cell. Although we will investigate the use of rectified power from the signal source without a storage cell, this method probably will not maintain adequate power supply to have the noise amplifier operating properly at all times. Furthermore, the first part of a transmission under high noise conditions may be lost since it is necessary to build up a power supply voltage before the voltage controlled attenuator would open up to allow high audio.
